

# Lab # 2: I/O Programming

## EC-102 – Computer Systems and Programming

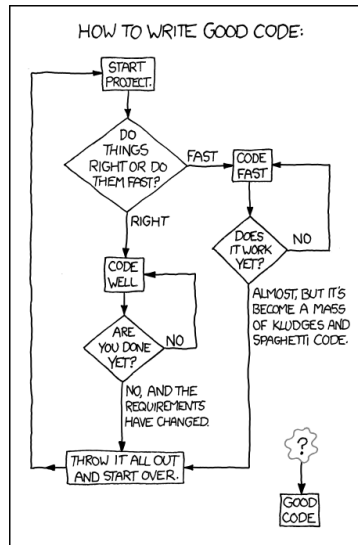

Usman Ayub Sheikh

School of Mechanical and Manufacturing Engineering (SMME),  
National University of Sciences and Technology (NUST)

September 14, 2015

# Outline

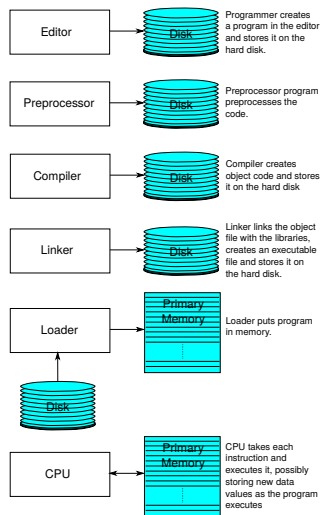

- 1 Basics of a Typical C++ Environment
- 2 First Program in C++
- 3 Arithmetic Operators
- 4 Fundamental C++ Data Types
- 5 Keywords in C++
- 6 Stream I/O
- 7 Assignment Statements
- 8 Solved Examples

# Basics of a Typical C++ Environment

## Phases of C++ Programs

- Edit
- Preprocess
- Compile
- Link
- Load
- Execute

# First Program in C++

```
1 // my first program in C++
2 #include <iostream>
3 using namespace std;
4 int main()
5 {
6     cout << "C++ is fun!" << endl;
7     return 0;
8 }
```

## Line-by-line Explanation

- ❶ Single line comment. In C++, there are two types of comments.
  - ▶ Single line – `//...`
  - ▶ Multi line – `/*...*/`
- ❷ Preprocessor directive to include input/output stream header file.
- ❸ A name-space where features of the C++ standard library such as `cout` or `endl` are declared.
- ❹ Function `main` appears at least once in every C++ program.

# First Program in C++

```
1 // my first program in C++
2 #include <iostream>
3 using namespace std;
4 int main()
5 {
6     cout << "C++ is fun!" << endl;
7     return 0;
8 }
```

## Line-by-line Explanation

- ⑤ Left brace begins function body.
- ⑥ `cout` belongs to name-space `std` and is used for console output, `<<` is known as a stream insertion operator. `endl` also belongs to name-space `std` and is used to insert a newline character.
- ⑦ `return` statement is used to terminate the execution of a function.

# Arithmetic Operators

C++ operation	C++ arithmetic operator
Addition	+
Subtraction	-
Multiplication	*
Division	/
Modulus	%

# Fundamental C++ Data Types

The C++ language offers several fundamental data types. These include

- `int` (-2,147,483,648 to 2,147,483,647) takes up **4 bytes**
- `short` (-32,768 to 32,767) takes up **2 bytes**
- `float` ( $3.4 \times 10^{-38}$  to  $3.4 \times 10^{38}$ ) takes up **4 bytes**
- `double` ( $1.7 \times 10^{-308}$  to  $1.7 \times 10^{308}$ ) takes up **8 bytes**
- `long double` ( $3.4 \times 10^{-4932}$  to  $3.4 \times 10^{4932}$ ) takes up **10 bytes**
- `char` (-128 to 127) takes up **1 byte**

# Fundamental C++ Data Types

- The strong data type system of C++ helps make sure that the data variables are used consistently and correctly.
- Type checking makes it easy for the compiler to spot errors during compilation and thus prevent such issues during execution of the program.
- Before a variable is used in C++, it must be declared and defined as follows,  
`int myage;`
- This line declares and defines a variable named `myage` as an integer.

# Fundamental C++ Data Types

- A declaration introduces the name `myage` to the compiler and attaches a specific meaning to it.
- A definition like this also instructs the compiler to allocate some memory for the variable.

# Fundamental C++ Data Types

When the compiler reads `myage` definition,

- It sets aside enough memory storage for an integer and uses the name `myage` to refer to it.
- It reserves the name `myage` so that it cannot be used by any other variable.
- It ensures that whenever this variable is used, it is used in a way that is consistent with the way an integer should be used.

# Keywords in C++

- Predefined reserved identifiers which have a special significance within the language.
- They are case-sensitive and cannot be used as identifiers in your program.
- They will be highlighted with a specific color by Visual Studio's editor as you write your code.
- If the keywords you type in do not appear highlighted, then they have been entered incorrectly.

# Keywords in C++

Here's a list of all the reserved keywords in standard C++.

<code>alignas</code>	<code>continue</code>	<code>friend</code>	<code>register</code>	<code>true</code>
<code>alignof</code>	<code>decltype</code>	<code>goto</code>	<code>reinterpret_cast</code>	<code>try</code>
<code>asm</code>	<code>default</code>	<code>if</code>	<code>return</code>	<code>typedef</code>
<code>auto</code>	<code>delete</code>	<code>inline</code>	<code>short</code>	<code>typeid</code>
<code>bool</code>	<code>do</code>	<code>int</code>	<code>signed</code>	<code>typename</code>
<code>break</code>	<code>double</code>	<code>long</code>	<code>sizeof</code>	<code>union</code>
<code>case</code>	<code>dynamic_cast</code>	<code>mutable</code>	<code>static</code>	<code>unsigned</code>
<code>catch</code>	<code>else</code>	<code>namespace</code>	<code>static_assert</code>	<code>using</code>
<code>char</code>	<code>enum</code>	<code>new</code>	<code>static_cast</code>	<code>virtual</code>
<code>char16_t</code>	<code>explicit</code>	<code>noexcept</code>	<code>struct</code>	<code>void</code>
<code>char32_t</code>	<code>export</code>	<code>nullptr</code>	<code>switch</code>	<code>volatile</code>
<code>class</code>	<code>extern</code>	<code>operator</code>	<code>template</code>	<code>wchar_t</code>
<code>const</code>	<code>false</code>	<code>private</code>	<code>this</code>	<code>while</code>
<code>constexpr</code>	<code>float</code>	<code>protected</code>	<code>thread_local</code>	
<code>const_cast</code>	<code>for</code>	<code>public</code>	<code>throw</code>	

- C++ input/output revolves around the notion of a data stream, where we can insert data into an output stream or extract data from an input stream.
- The standard output stream to the screen is referred to as `cout`.
- The standard input stream from the keyboard is referred to as `cin`.

# Assignment Statements

- The statement which assigns some value to a variable is called an assignment statement.
- The `=` operator is used to assign a value to a variable.
- In an assignment statement such as `my age = 25;`, the variable `myage` has been assigned a value of 25.

# Solved Example 1

## Algorithm

- 1 Start
- 2 Declare variables  $a$ ,  $b$  and  $sum$
- 3 Initialize  $a$  and  $b$  to appropriate values
- 4 Add  $a$  and  $b$  and assign the result to  $sum$
- 5 Display  $sum$
- 6 Stop

## Flowchart

# Solved Example 1

## Code

```
1 // this program displays the sum
  of two numbers
2 #include <iostream>
3 using namespace std;
4 int main()
5 {
6     int a, b, sum;
7     a = 20;
8     b = 30;
9
10    sum = a + b;
11
12    cout << sum << endl;
13    return 0;
14 }
```

## Flowchart

# Solved Example 2

## Algorithm

- ① Start
- ② Declare variables  $a$ ,  $b$  and  $sum$
- ③ Read values of  $a$  and  $b$
- ④ Add  $a$  and  $b$  and assign the result to  $sum$
- ⑤ Display  $sum$
- ⑥ Stop

## Flowchart

# Solved Example 2

## Code

```
1 // this program displays the sum of two
  numbers entered by the user
2 #include <iostream>
3 using namespace std;
4 int main()
5 {
6     int a, b, sum;
7     cout << "Enter first number: ";
8     cin >> a;
9     cout << "Enter second number: ";
10    cin >> b;
11
12    sum = a + b;
13
14    cout << "The sum of two numbers is: ";
15    cout << sum << endl;
16
17    return 0;
18 }
```

## Flowchart
